

Kline's Rules for How to Fool Yourself with SEM

Don't Have a Plan

(ok, this one is mine)

A screenshot of a Facebook comment thread. The main post is by Amelia Hoover, titled "I CAN HAS ESTIMITS!!!", posted on Thursday at 13:02. Below it, a notification says "You and 2 others like this." The thread contains 12 comments from various users, including Rob Person, Amelia Hoover, David Mister, David January, Emily Clough, Branen Salmon, Jarrett Byrnes, and Amelia Hoover again. The comments are humorous and often contain misspellings or puns related to the original post's title.

Amelia Hoover I CAN HAS ESTIMITS!!!
Thurs at 13:02 · Comment · Unlike

You and 2 others like this.

Rob Person BUT IZ THEY CANS BE KONSISTENT???
Thurs at 13:50

Amelia Hoover KONFLUJUNS INNRVAL KONSISTENTLY INKLOOD ZERO. DO OVERS!!!
Thurs at 13:52

David Mister ...GEEKcats?
Thurs at 14:00

David January All I can say is "wow".
Thurs at 14:55

Amelia Hoover update: I CAN HAS INTERACKSHIN TURM!
Thurs at 17:35

Emily Clough BAYESMENT CAT ATTACK!
Thurs at 22:23

Amelia Hoover oh snap.
Thurs at 22:26

Branen Salmon This is the most amazing thing I have ever witnessed.
Fri at 00:16

Amelia Hoover oh, this is nothing. a couple of years ago I wrote a whole program in LOLpython.
Fri at 02:03

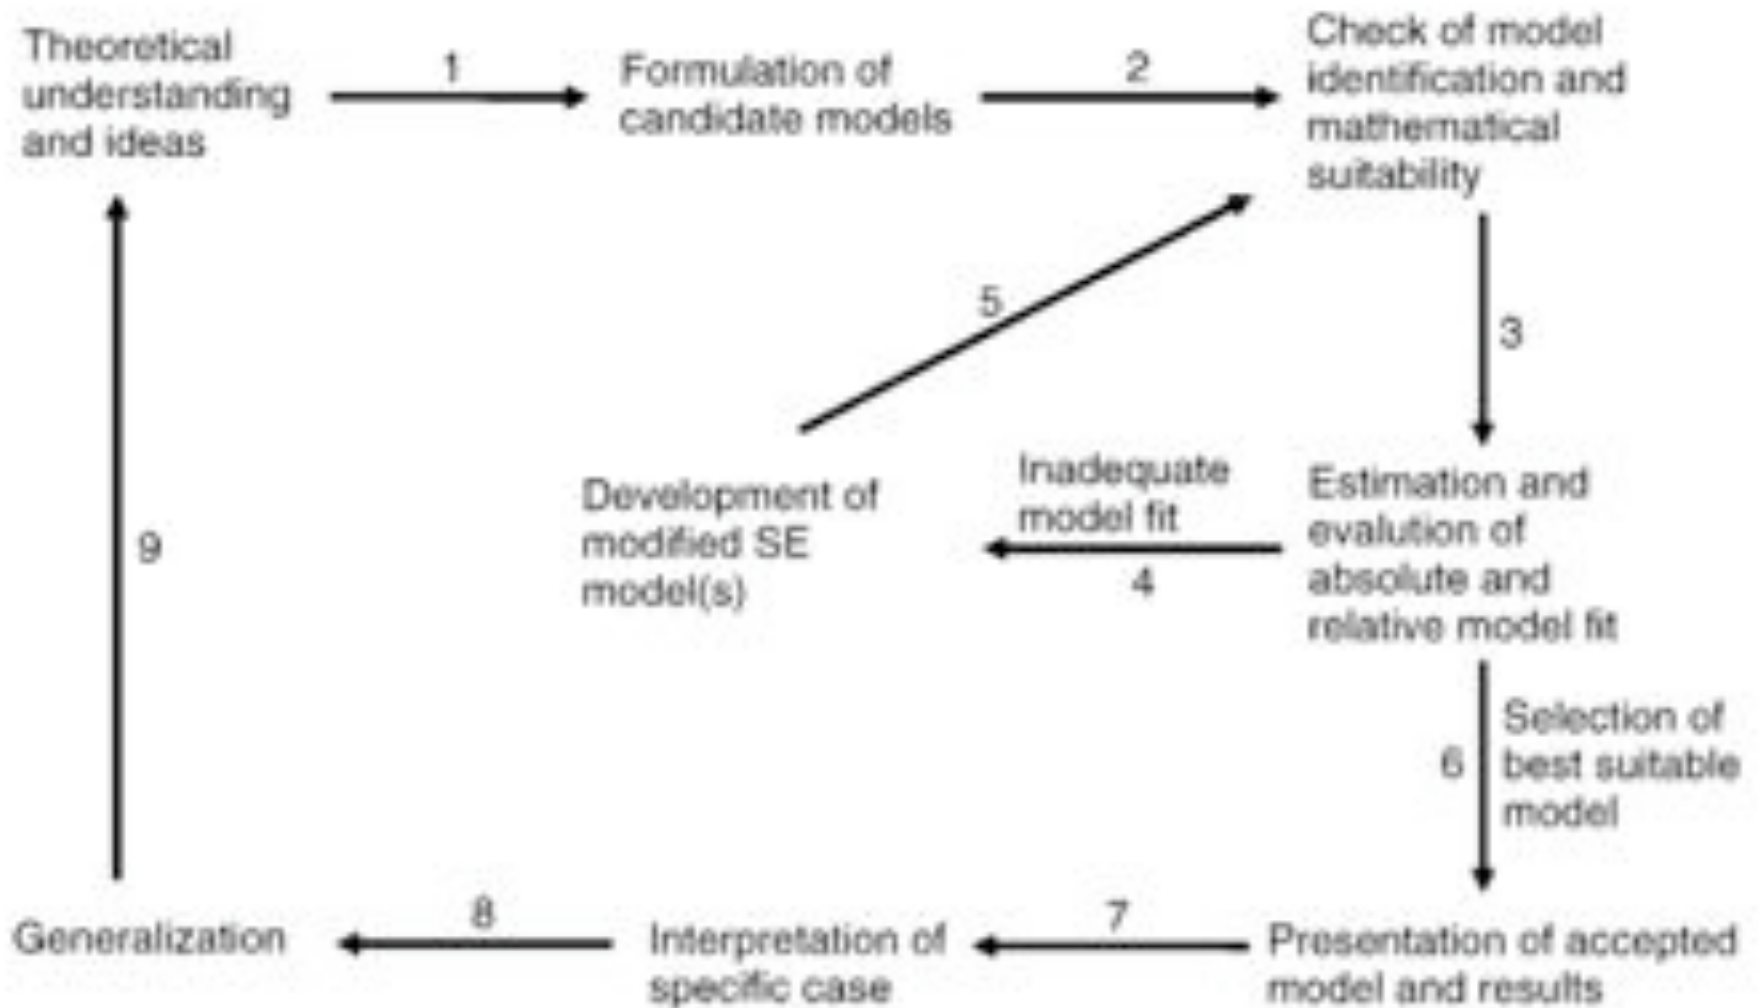

Rob Person OOPS I HAZ MADE P-VALYOO ON TEH KARPITZ.
Fri at 02:23

Jarrett Byrnes IM IN UR AICZ, MAXMIZIN MAH LIKLIHOODZ!
Fri at 11:34 · Delete

Amelia Hoover I will cherish this comment thread forever.
Fri at 12:16

Don't Have a Plan

(ok, this one is mine)

Tripping at the Starting Line: Model Specification

Specify the model after the data are collected

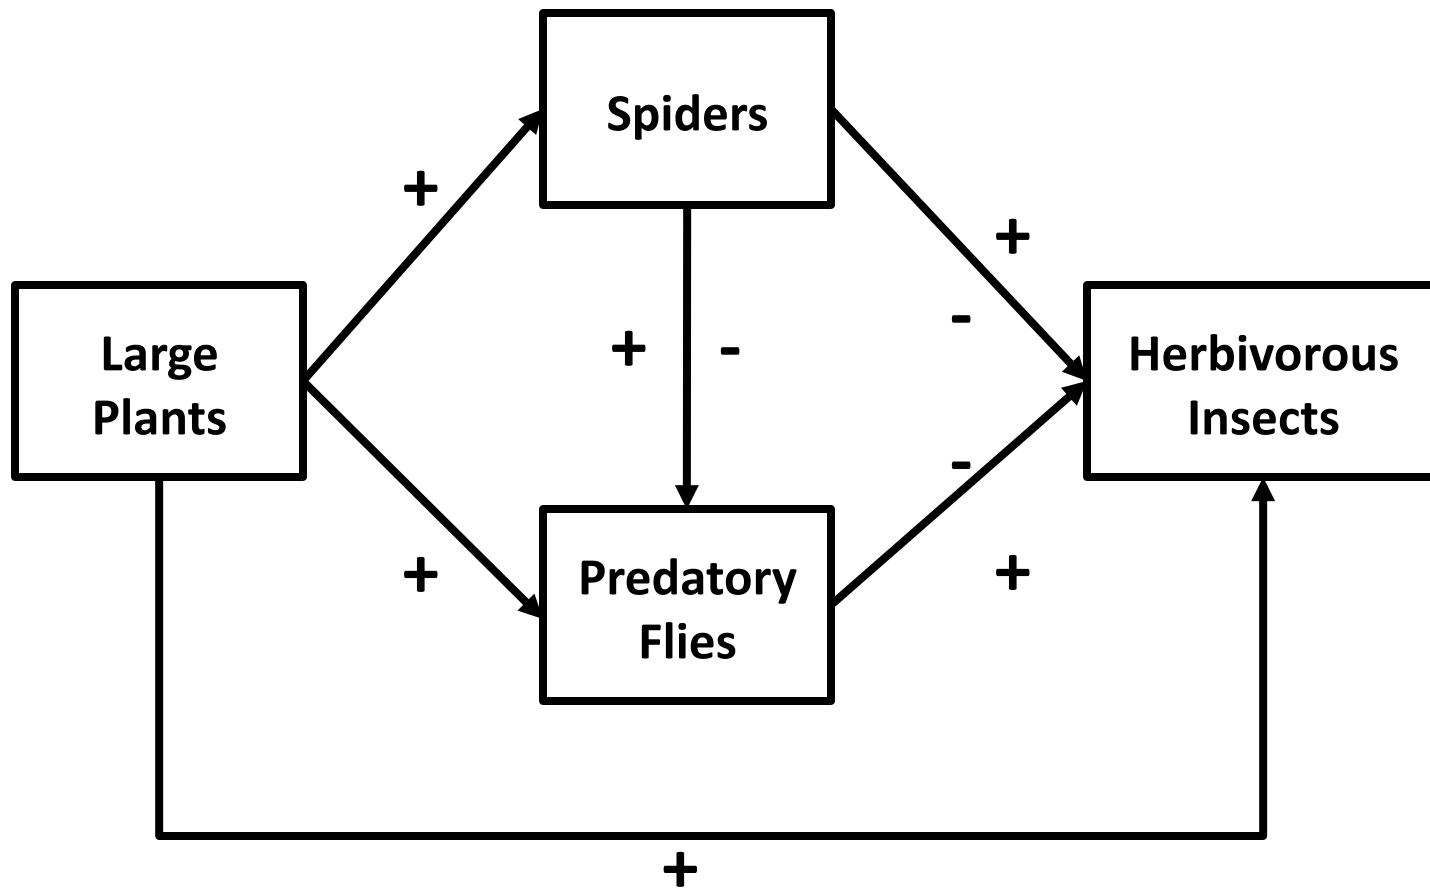

You must ask:

Will the data
provided by
adequate?

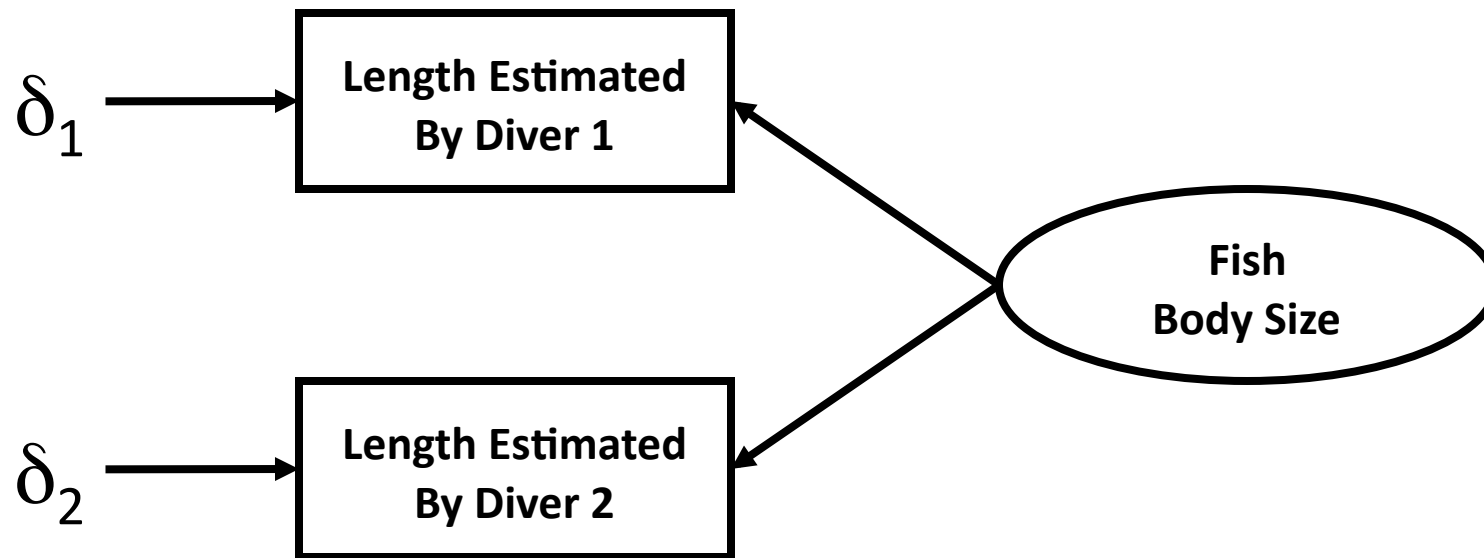

What did they miss?

Can it be modeled?

Omit causes that are correlated with variables in the structural model

Fail to have a sufficient number of indicators for latent variables

What if these estimates are wildly divergent? Solution becomes unstable.

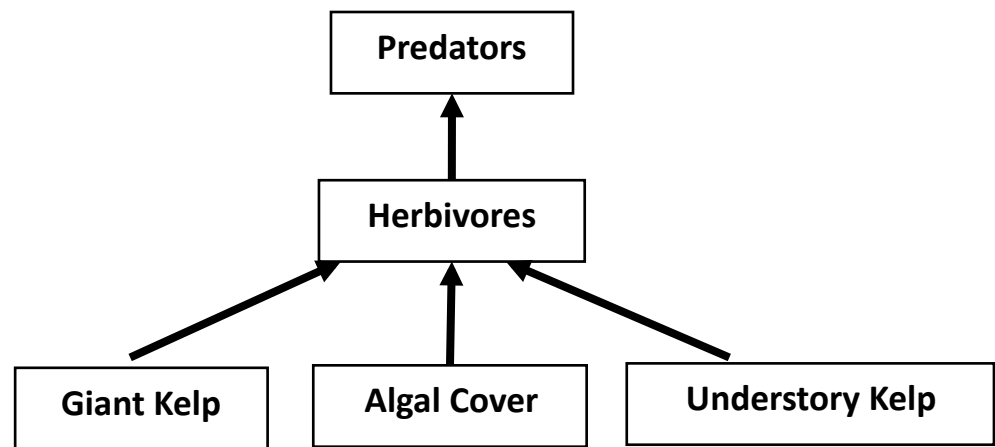

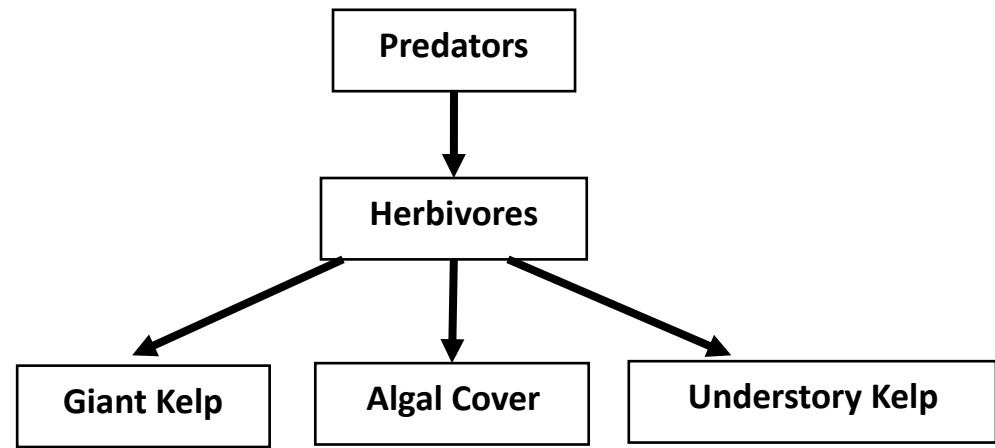

Use indicator variables that do not match concepts contained in latent variables

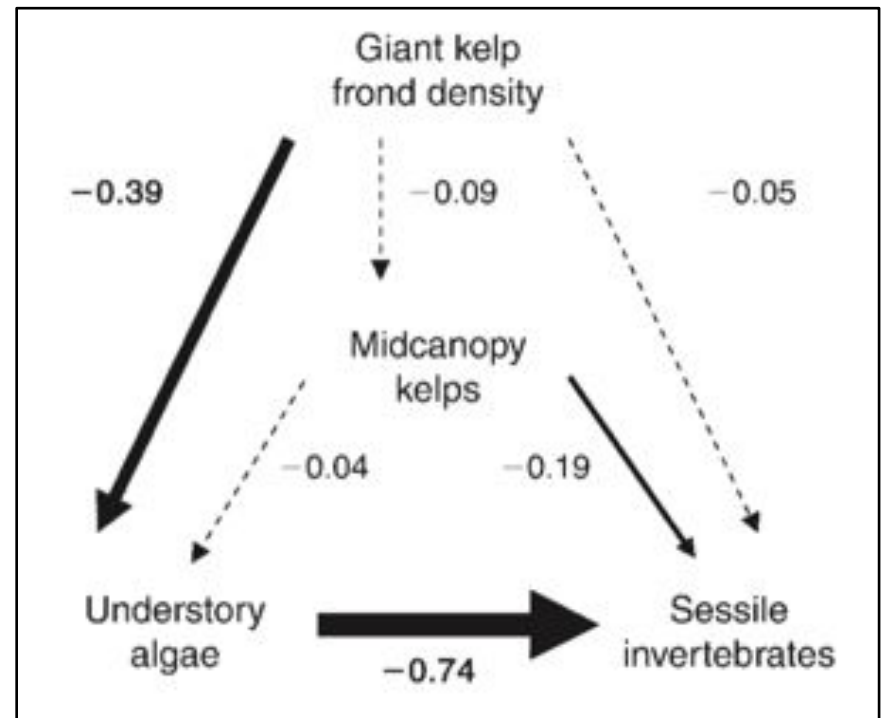

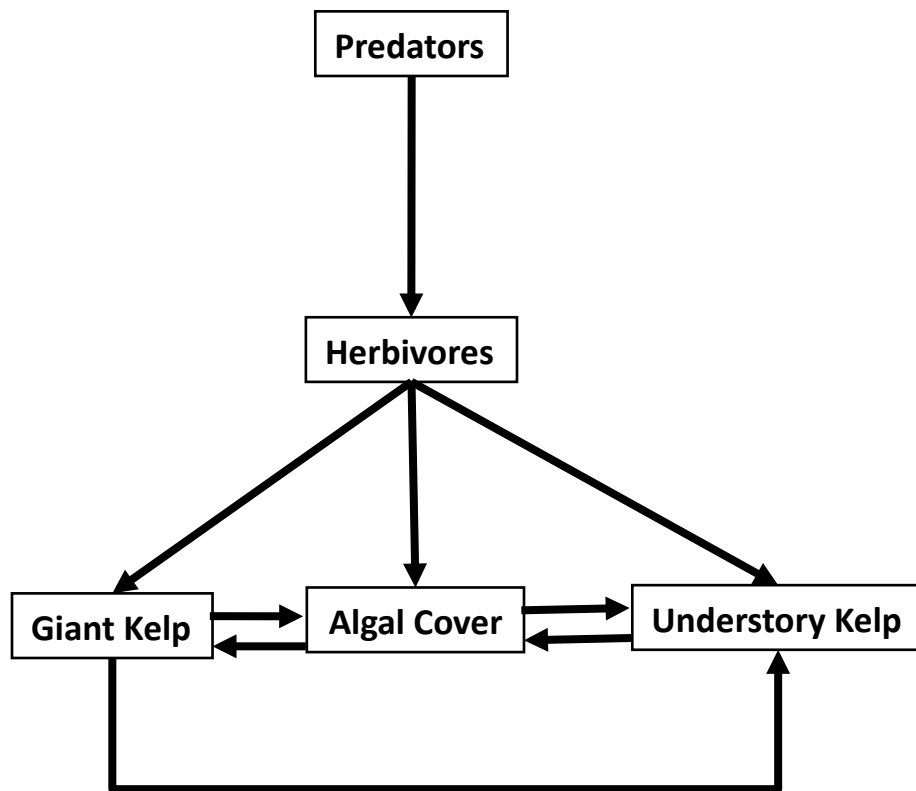

Fail to give careful consideration to directionality

- These models describe completely different phenomena

- If these models have the same coefficient estimates, what does that mean?

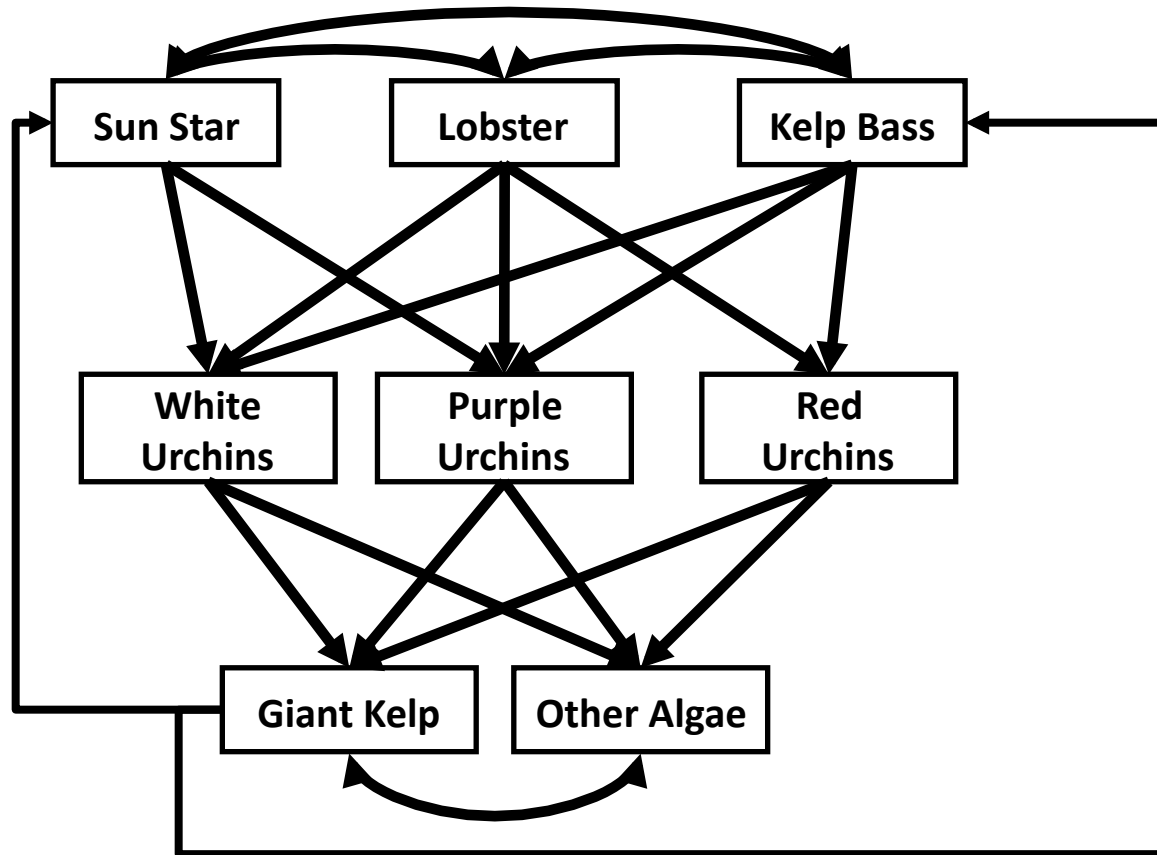

Specify feedbacks as a way to mask uncertainty about directionality

Arkema et al. 2010

Forget the Goal of Parsimony

What will we learn from this model?

How is it being a multivariate model useful?

Would a simpler model better represent processes we can detect given our data?

Will including all of these paths lead to excessive parameter uncertainty?

Add unexplained covariances without substantive reasoning

- Yes, everything in the world is correlated.
- You will miss some substantive correlations in any model you create.
- But...if you have no reason to include correlated errors, why should you?

Specify that indicators load on more than one latent variable without a substantive reason

If one of these variables is an indicator of another latent variable, it must be from the non-shared variation. Otherwise, what does this variable mean? Solution potentially unstable.

Improper Care and Feeding: Data

Don't check the accuracy of data inputs or coding

YEAR	SITE	TRANSECT	QUAD	FRONDS	HLD_DIAM	
2000	BULL		1	20	2	-99999
2000	BULL		1	20	4	7
2000	BULL		1	20	2	-99999
2000	BULL		1	20	2	-99999
2000	BULL		1	20	2	-99999
2000	BULL		1	20	2	-99999
2000	BULL		1	40	2	-99999

- -99999 was the code for missing data.
- I had no clue.
- My models gave some *very* strange estimates.

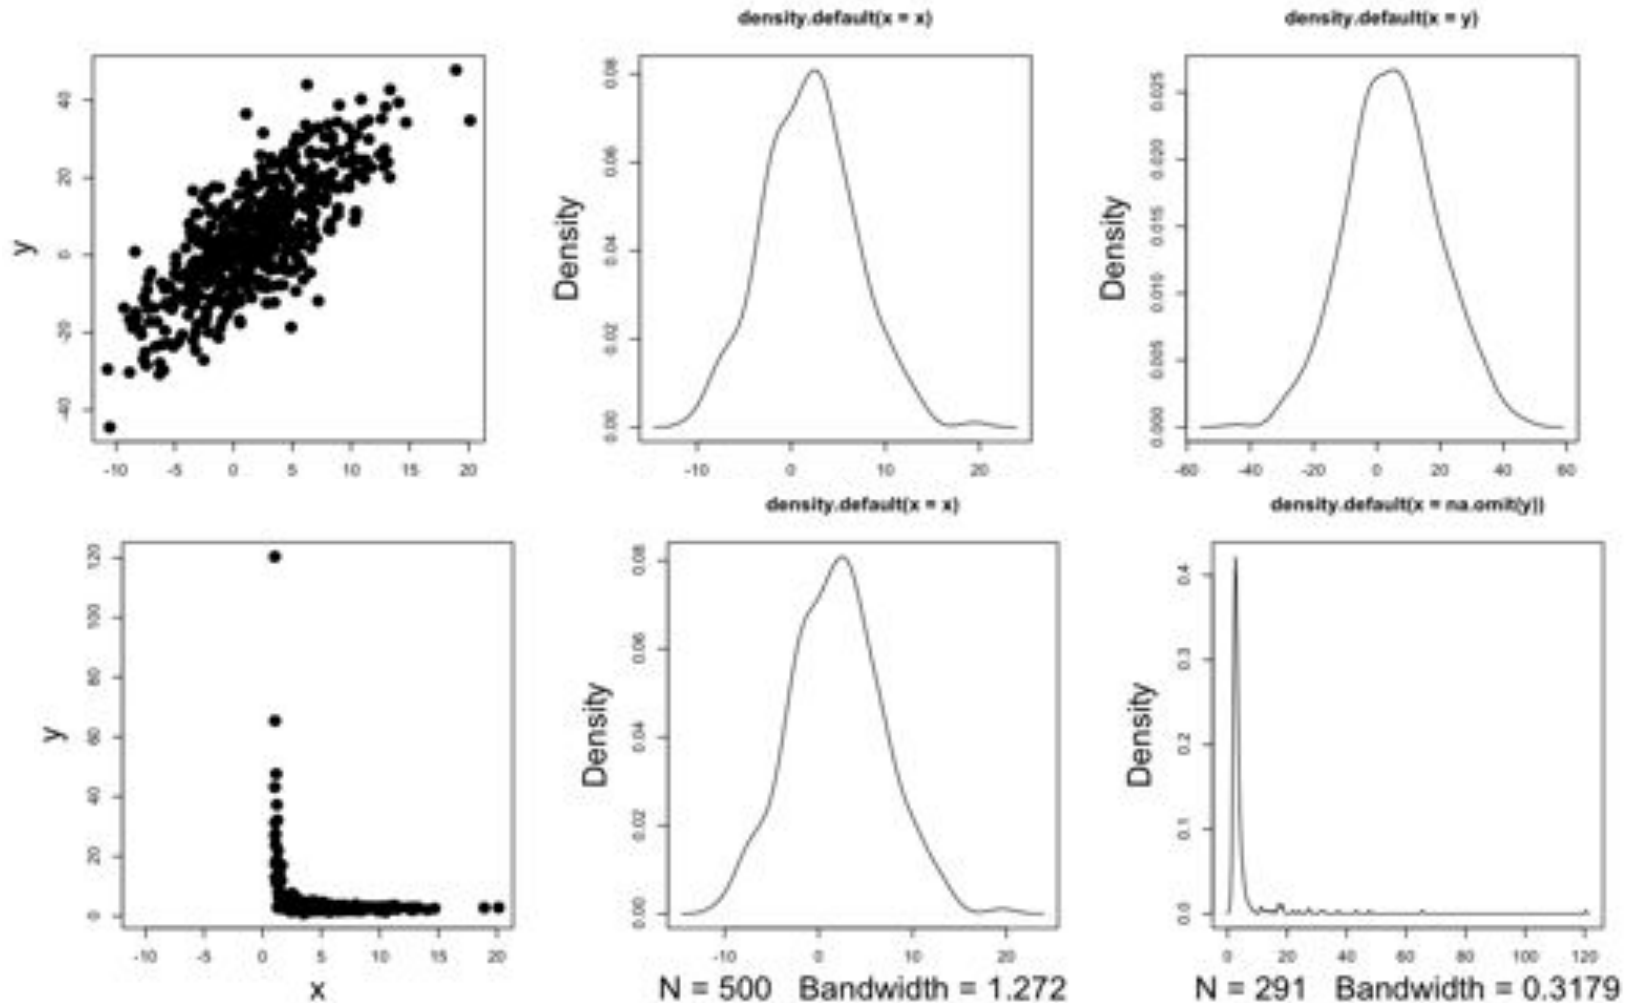

Ignore whether the pattern of missing data loss is random or systematic

YEAR	SITE	MAX_WAVE_HEIGHT_M
1996	BULL	1.452661106
1997	BULL	NA
1998	BULL	2.614931561

1998	MOHK	2.337630923
1998	MOHK	NA
2000	MOHK	1.592523562

- There is real information loss when the data is missing systematically.
- Estimates will not encompass true range of variation.
- Missing data imputation is a **big** field.

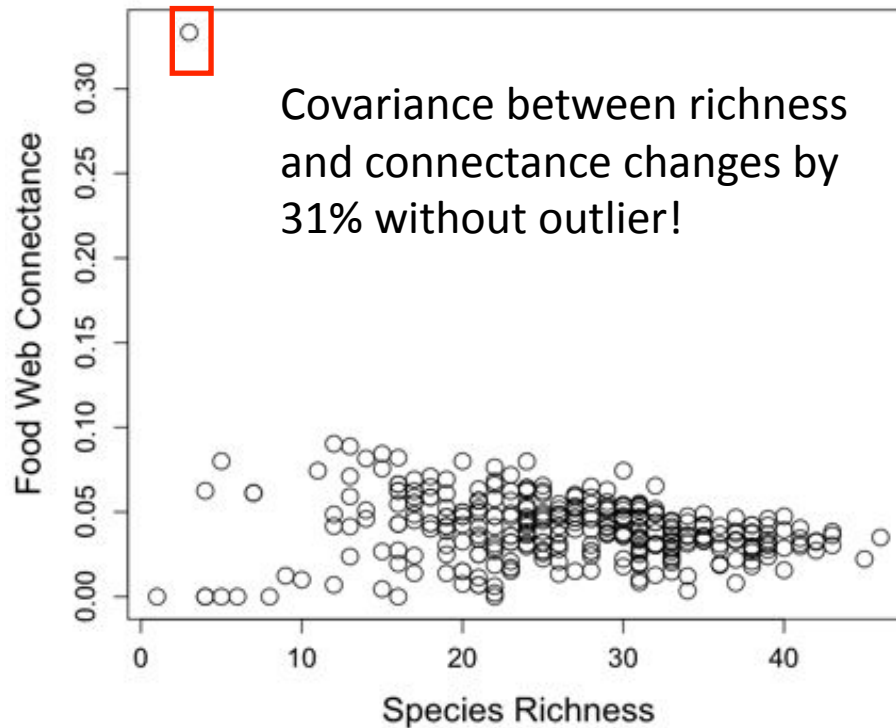

Failing to examine data for multivariate normality

χ^2 for TopDown+BottomUp model=58.11, $p < 0.0001$

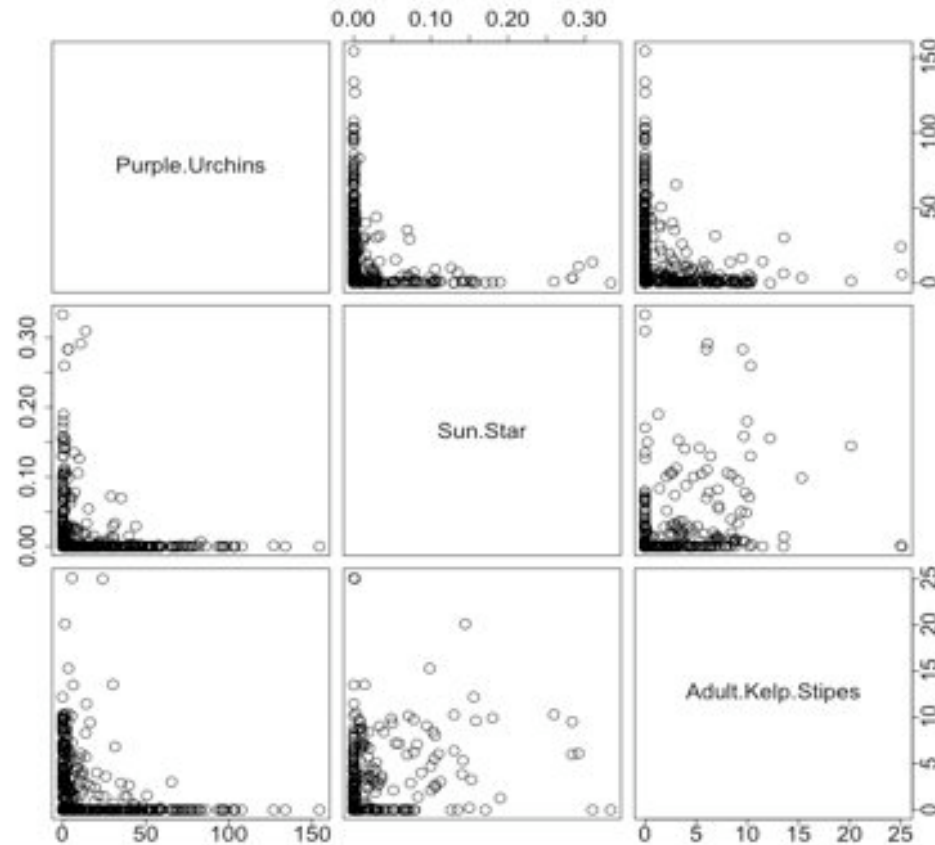

χ^2 for TopDown+BottomUp model after SB correction=25.49, $p = 0.18$

Don't screen for outliers

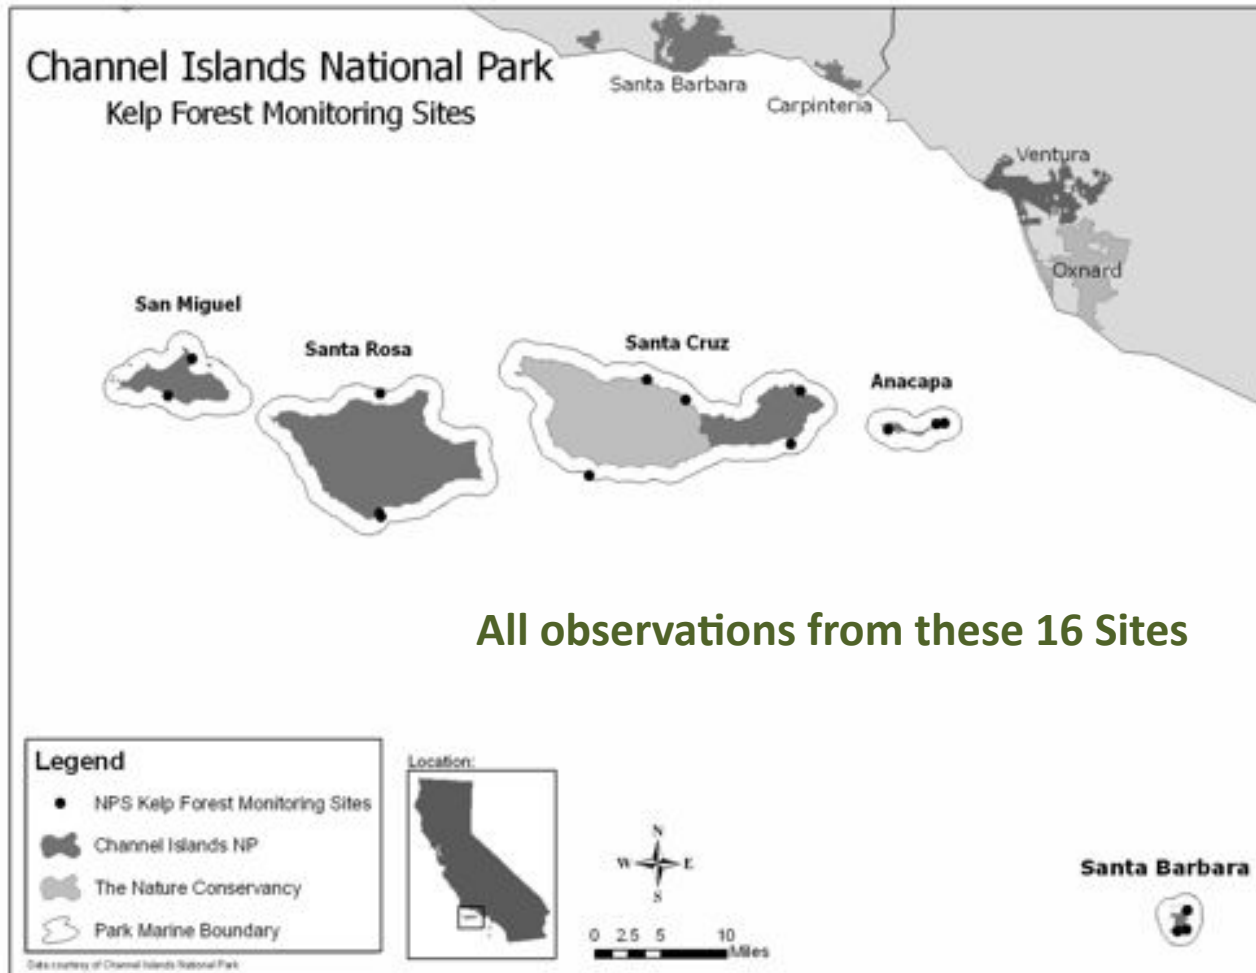

- Can greatly influence variances and covariances – influences paths in which variable with outlier is not directly involved.
- But...there's information in them that's outliers!

Assume that all relations are linear without checking

- If do not want to transform your data (and there are some very good reasons for this), use piecewise approaches – maybe Bayes!

Ignore the lack of independence between observations

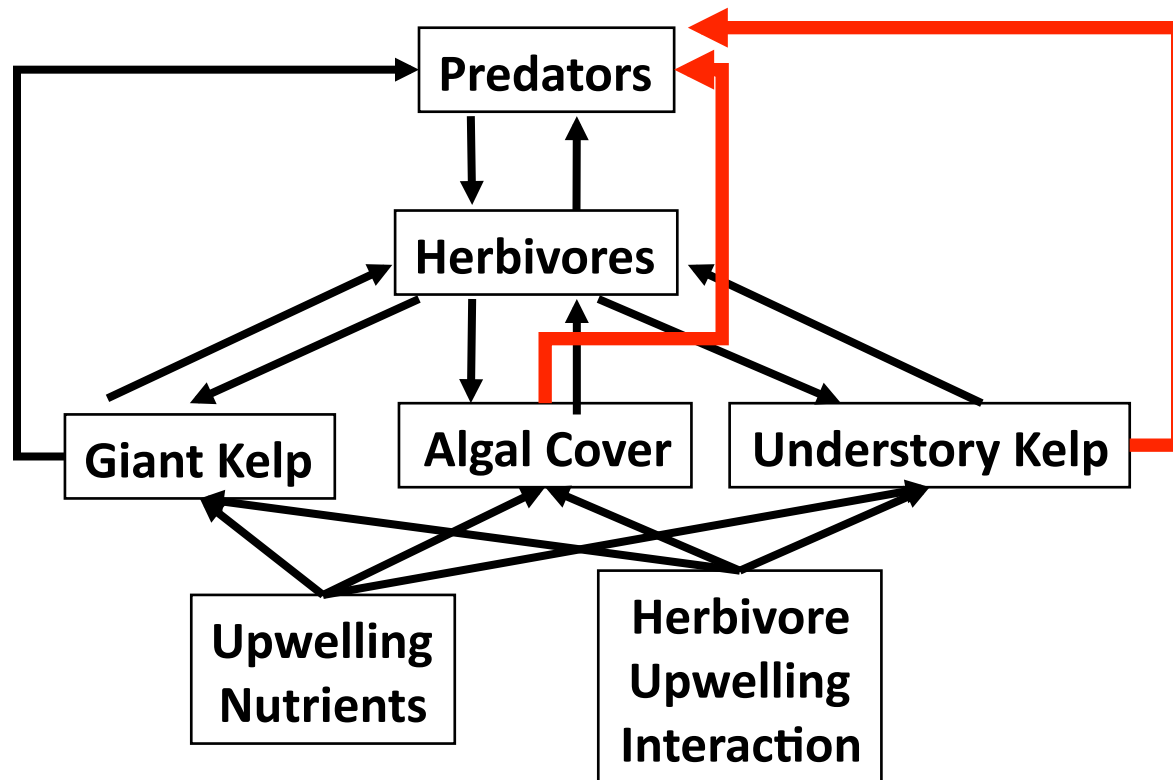

Solutions: Autoregressive models, Incorporate hierarchies explicitly, Multilevel SEM, Moran's I

Checking Critical Thinking at the Door: Analysis and Respecification

Respecify a model based entirely on statistical criteria

Lagrange multipliers can be dangerous things...

Fail to check the accuracy of your computer code

```
pred.model<-specify.model()
Sun.Stars -> Purple.Urchins, star.purp, NA
Kelp.Bass -> Purple.Urchins, kelpbass.purp, NA
Lobster -> Purple.Urchins, lobster.purp, NA
Purple.Urchins -> Adult.Kelp.Stipes, purp.kelp, NA
Purple.Urchins <-> Purple.Urchins, urchin.var, NA
Adult.Kelp.Stipes<->Adult.Kelp.Stipes, kelp.var, NA
Rock.Percent -> Adult.Kelp.Stipes, rock.kelp, NA
Rock.Percent -> Purple.Urchins, rock.purp, NA
```

```
> pred.fit<-sem(pred.model, pred.cov, N=length(kfm[,1]), fixed.x=c("Kelp.Bass", "Lobster",
"Sun.Star", "Rock.Percent"), debug=T)
```

observed variables:

```
[1] "1:Purple.Urchins"      "2:Kelp.Bass"          "3:Lobster"           "4:Adult.Kelp.Stipes"
"5:Rock.Percent"
```

latent variables:

```
[1] "6:Sun.Stars"
```

Fail to carefully inspect the solution for problems

1. Do you have any Heywood cases (estimates of variance <0)?
2. How well explained are your endogenous variables?
3. Any “surprises”? And not the kind that leads to birthday cake.

Report only standardized estimates

- $r_{xy} = B_{xy} * sd(x) / sd(y)$ -> what is the range of variability with your x and y? (see relative range standardizations)
- Standardized coefficients useful for comparisons within a model.
- If you are using your model for predictive purposes, the unstandardized estimate is more useful.

Analyze variables so highly correlated the solution is unstable

Neither variable provides unique information.

Estimate a complex model with a small sample size

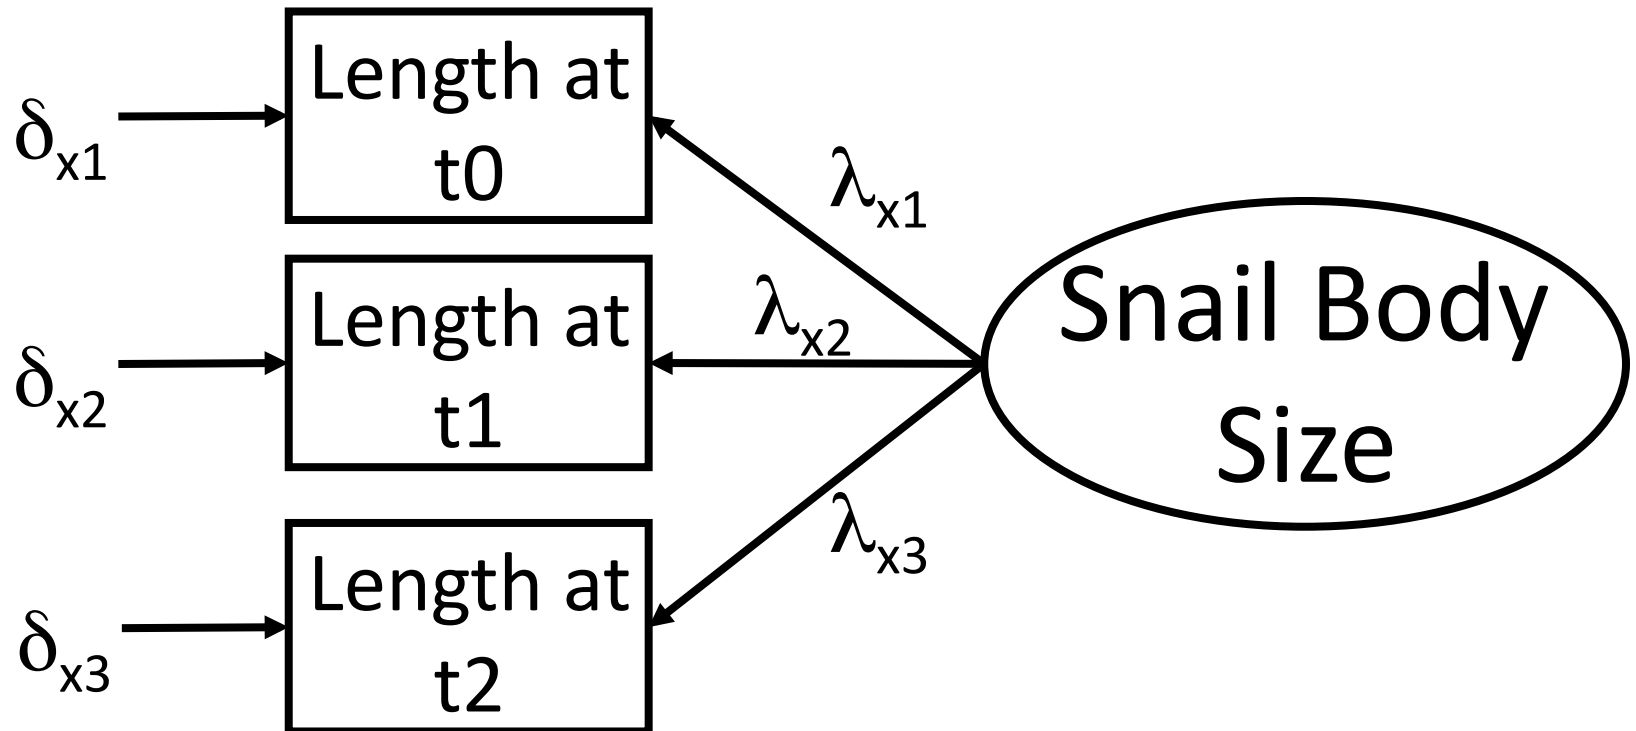

- $N=5-10$ per parameter
- Aids in stable solutions
- Influences significance testing of individual paths
 - But beware the fallacy of too large of a sample size = highly significant correlations
- This is even more of a problem for fitting criteria other than F_{ML}

Set scales for latent variables inappropriately

Setting a scale determines the definition of your latent variable.

Set scales for latent variables inappropriately

For example, what does setting a scale mean for repeated measures?

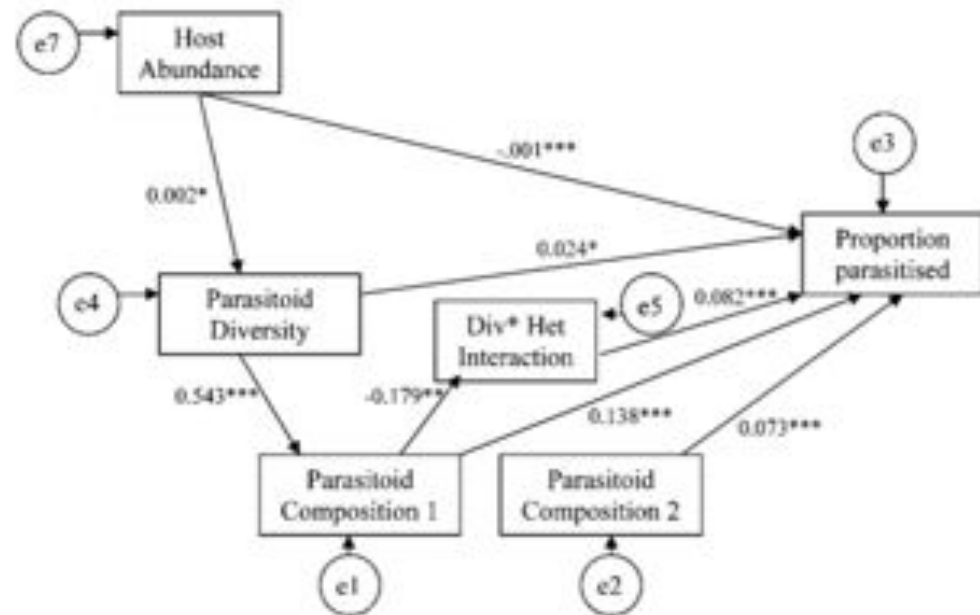

Ignore the problem of start values, or provide bad start values

- Start values close to your solution will speed convergence.
- Start values far from your solution will delay convergence, and can lead you into local solutions.
- If your intuition says that a bad fit is incorrect, try varying start values -> your results should be robust anyway!

The Garden Path: Interpretation

Look Only at Path Significance and Not Overall Fit (yes, people do this)

No fit indices reported.

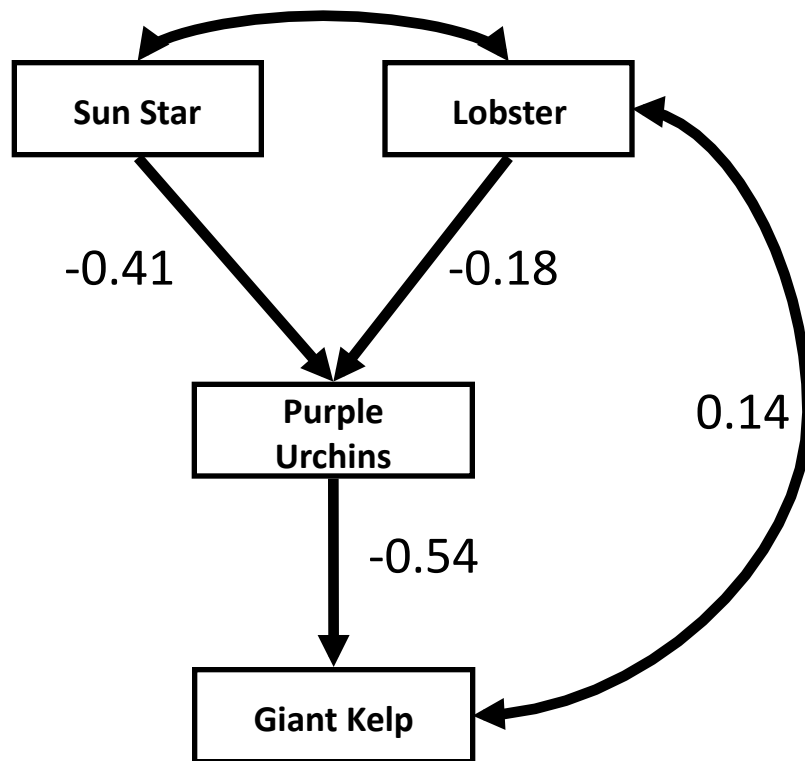

Email with author (I had some questions about the nonlinearity) revealed that model did not fit the data.

(however, SEM was tacked on to support regression results due to a reviewer – I still believe the message in this paper and think it's a pretty cool attempt to get at some complicated concepts)

Interpret good fit as the model being “proved”

- $P(\text{Data} \mid \text{Hypothesis})$ = Probability of observing the data at hand given a hypothesis proposed.
- High p values **DOES NOT** equal good support for a hypothesis.
- P values are useful only as support for **rejecting** a hypothesis.
- Data can be consistent with one hypothesis and still conform to many others.

Look only at indexes of overall fit and ignore other information about fit; interpret fit indices as meaning that endogenous variables are strongly predicted

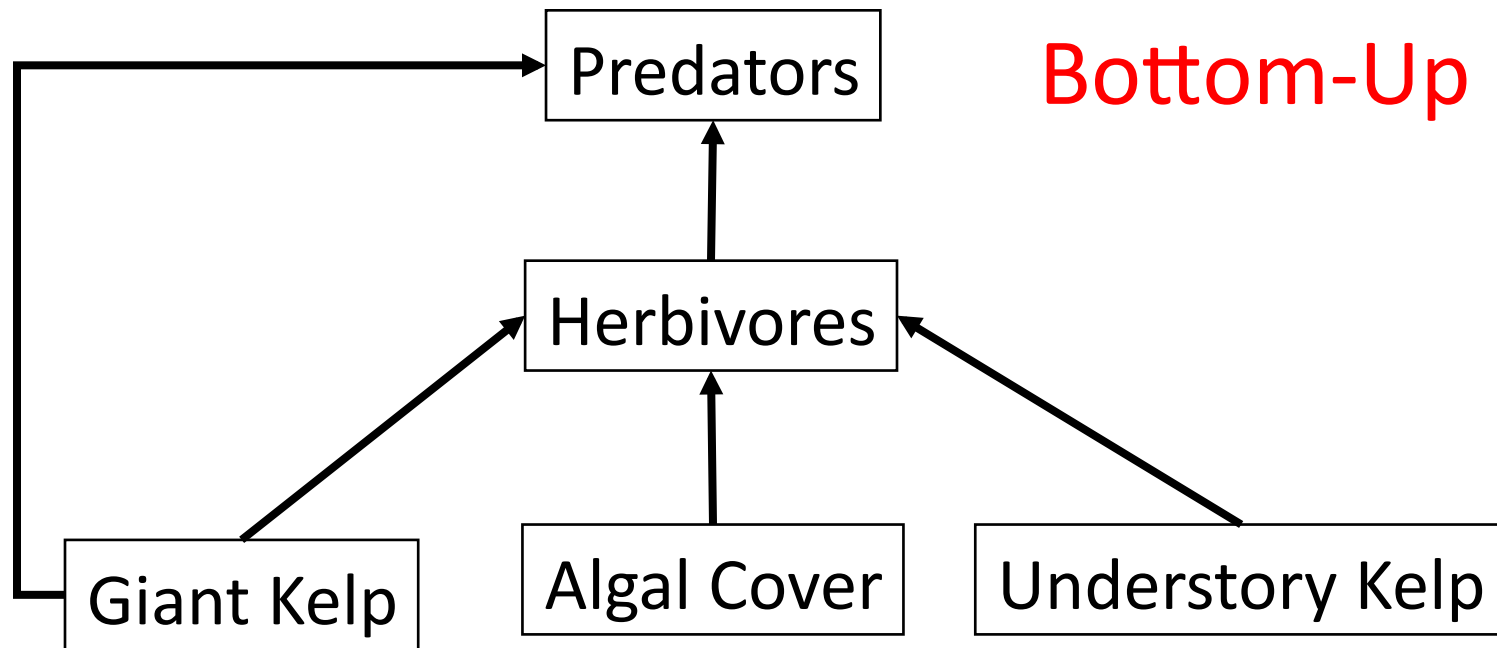

$$\chi^2 = 2.58, df = 1, P = 0.108$$

$$R^2_{\text{lobster}} = 0.09$$

$$R^2_{\text{urchins}} = 0.17$$

$$R^2_{\text{kelp}} = 0.31$$

Rely solely on statistical criteria in model evaluation

What if you fit this model, and all paths were significant. You have good model fit. Variables were even well predicted, but...

ALL OF THE PATH COEFFICIENTS WERE NEGATIVE

Interpret the standardized solution in inappropriate ways

TABLE 3

CALCULATED PATH EQUATIONS OF THE EFFECT OF KANGAROO RATS ON OTHER RODENTS

Treatment	Path Equation	e_y
Harvest mice:		
A	$-.303 = -.230 - .073$.85
B	$-.710 = -.723 + .014$.66
C	$-.760 = -.450 - .310$.57
Pocket mice:		
A	$-.212 = -.150 - .062$.91
B	$-.554 = -.561 + .006$.82
C	$-.362 = .045 - .407$.67

Groups differed in variation, producing different standardized coefficients!

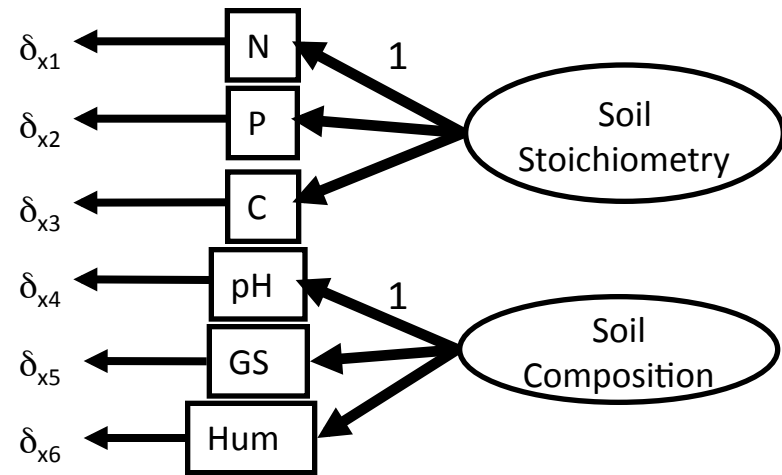

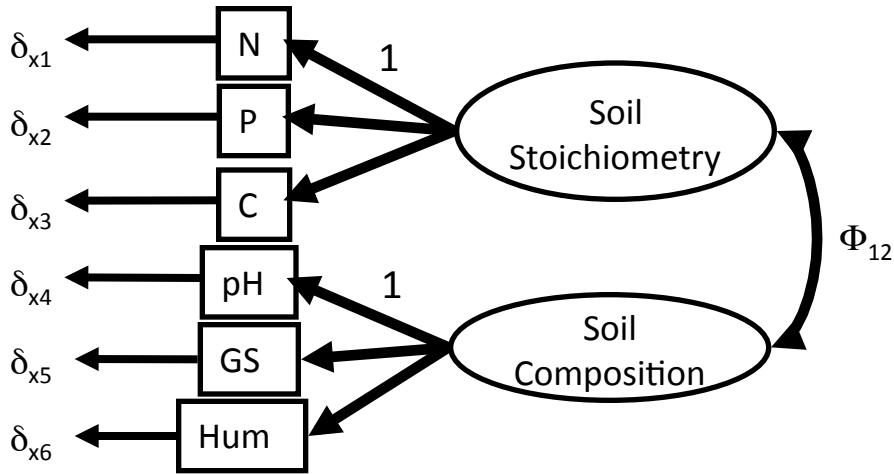

Smith et al. 1997

versus

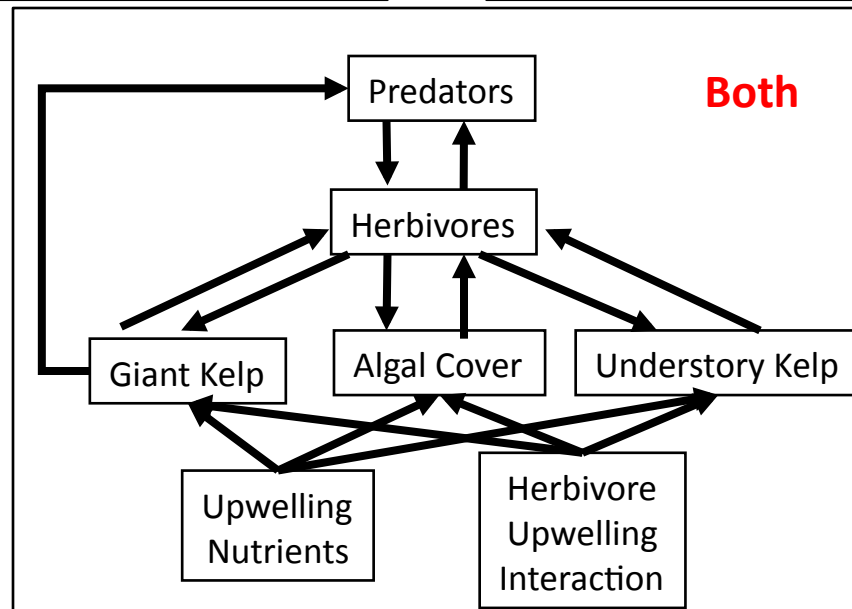

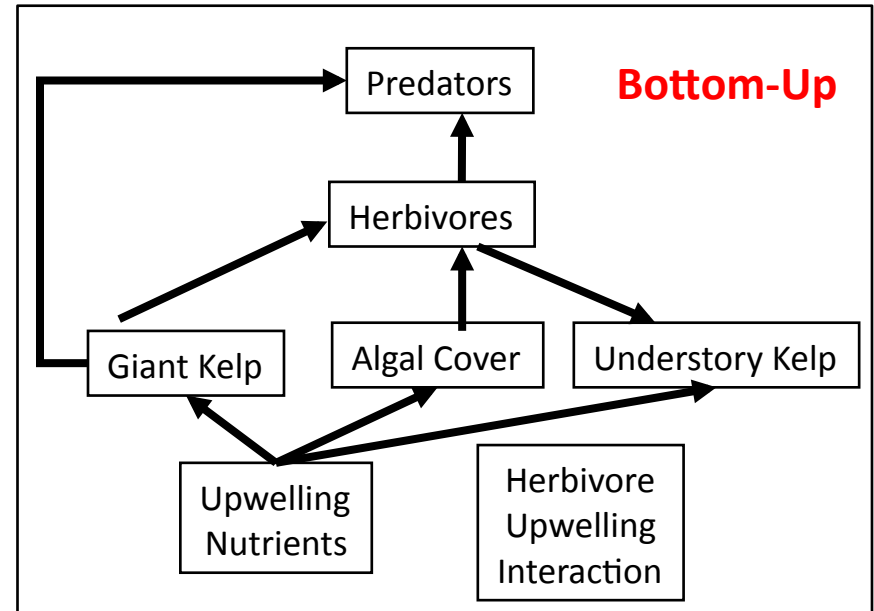

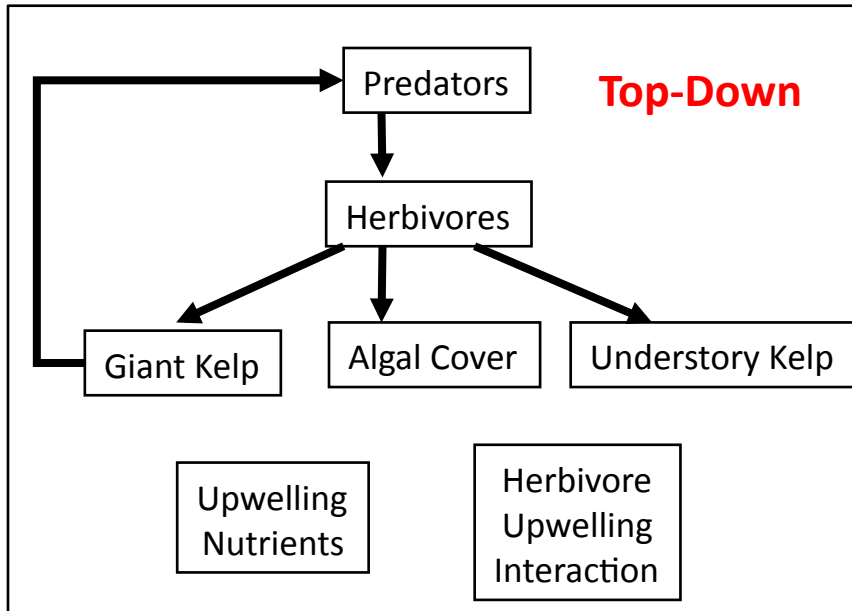

<i>Harvest mice</i>	<i>Pocket mice</i>
<i>A. Multigroup goodness-of-fit statistic</i>	
N for multigroup analysis = 38	N for multigroup analysis = 38
χ^2 with 9 df = 7.8400 ($P = .5503$)	χ^2 with 8 df = 9.6308 ($P = .2919$)
Group A $\chi^2 = 3.2771$	Group A $\chi^2 = 4.6998$
Group B $\chi^2 = 1.7419$	Group B $\chi^2 = 2.2934$
Group C $\chi^2 = 2.8210$	Group C $\chi^2 = 2.6376$

Grace and Pugesek 1998

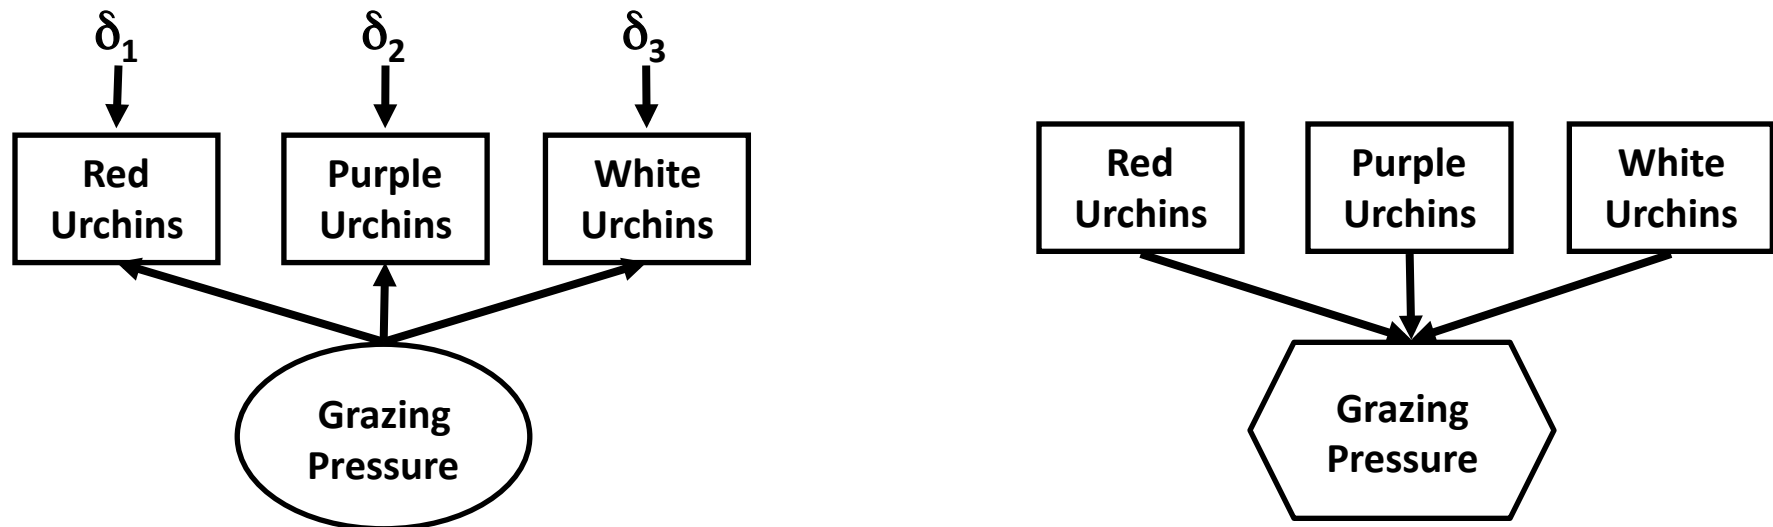

Fail to consider equivalent models

Fail to consider non-equivalent alternative models

Believe that naming a latent variable with a concept makes it so

What information does this latent variable really convey? How did it differ from the composite variable we came to believe was correct?

Beware of the fallacy of naming!

Believe that a strong SEM analysis can compensate for a poor study

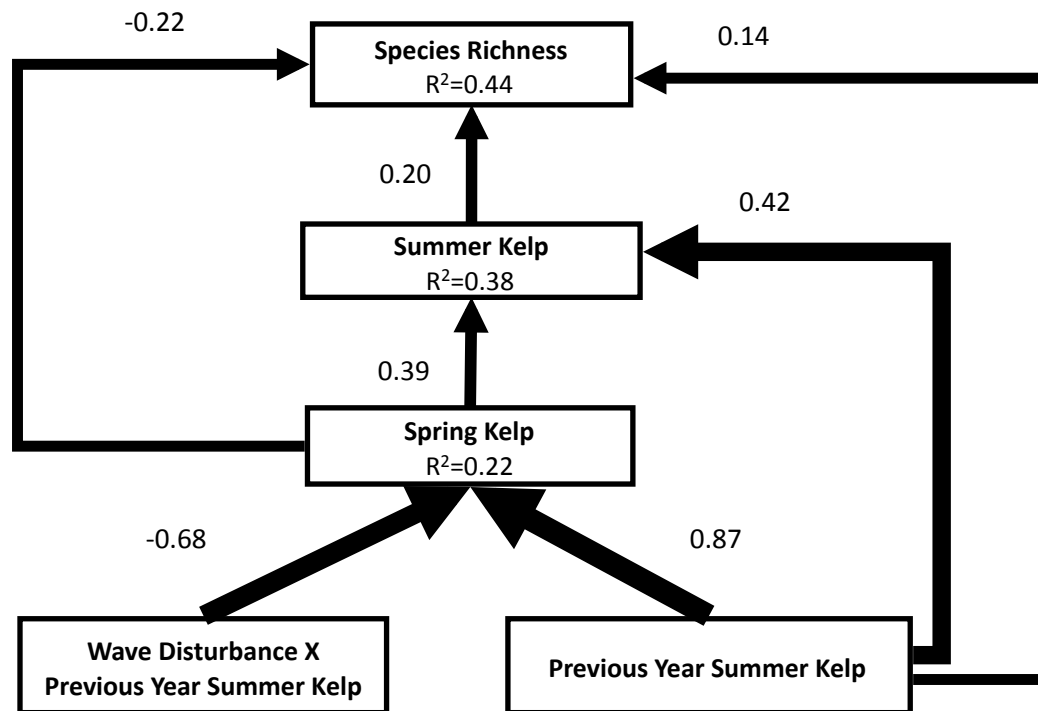

TABLE 3

CALCULATED PATH EQUATIONS OF THE EFFECT OF KANGAROO RATS ON OTHER RODENTS

Treatment	Path Equation	e_y
Harvest mice:		
A	$-.303 = -.230 - .073$.85
B	$-.710 = -.723 + .014$.66
C	$-.760 = -.450 - .310$.57
Pocket mice:		
A	$-.212 = -.150 - .062$.91
B	$-.554 = -.561 + .006$.82
C	$-.362 = .045 - .407$.67

- Standardized Coefficients varied wildly
- Indirect effects not detected in 2 of 3 path models

Fail to report enough information so that others can reproduce your model

- If you have a simplified conceptual diagram, include the gory details.

What should I report?

- A clear path diagram
- Relevant fit statistics (χ^2)
- Unstandardized path coefficients and evaluation of whether they are different from zero
- Covariance matrix and/or correlation, standard deviation, and means

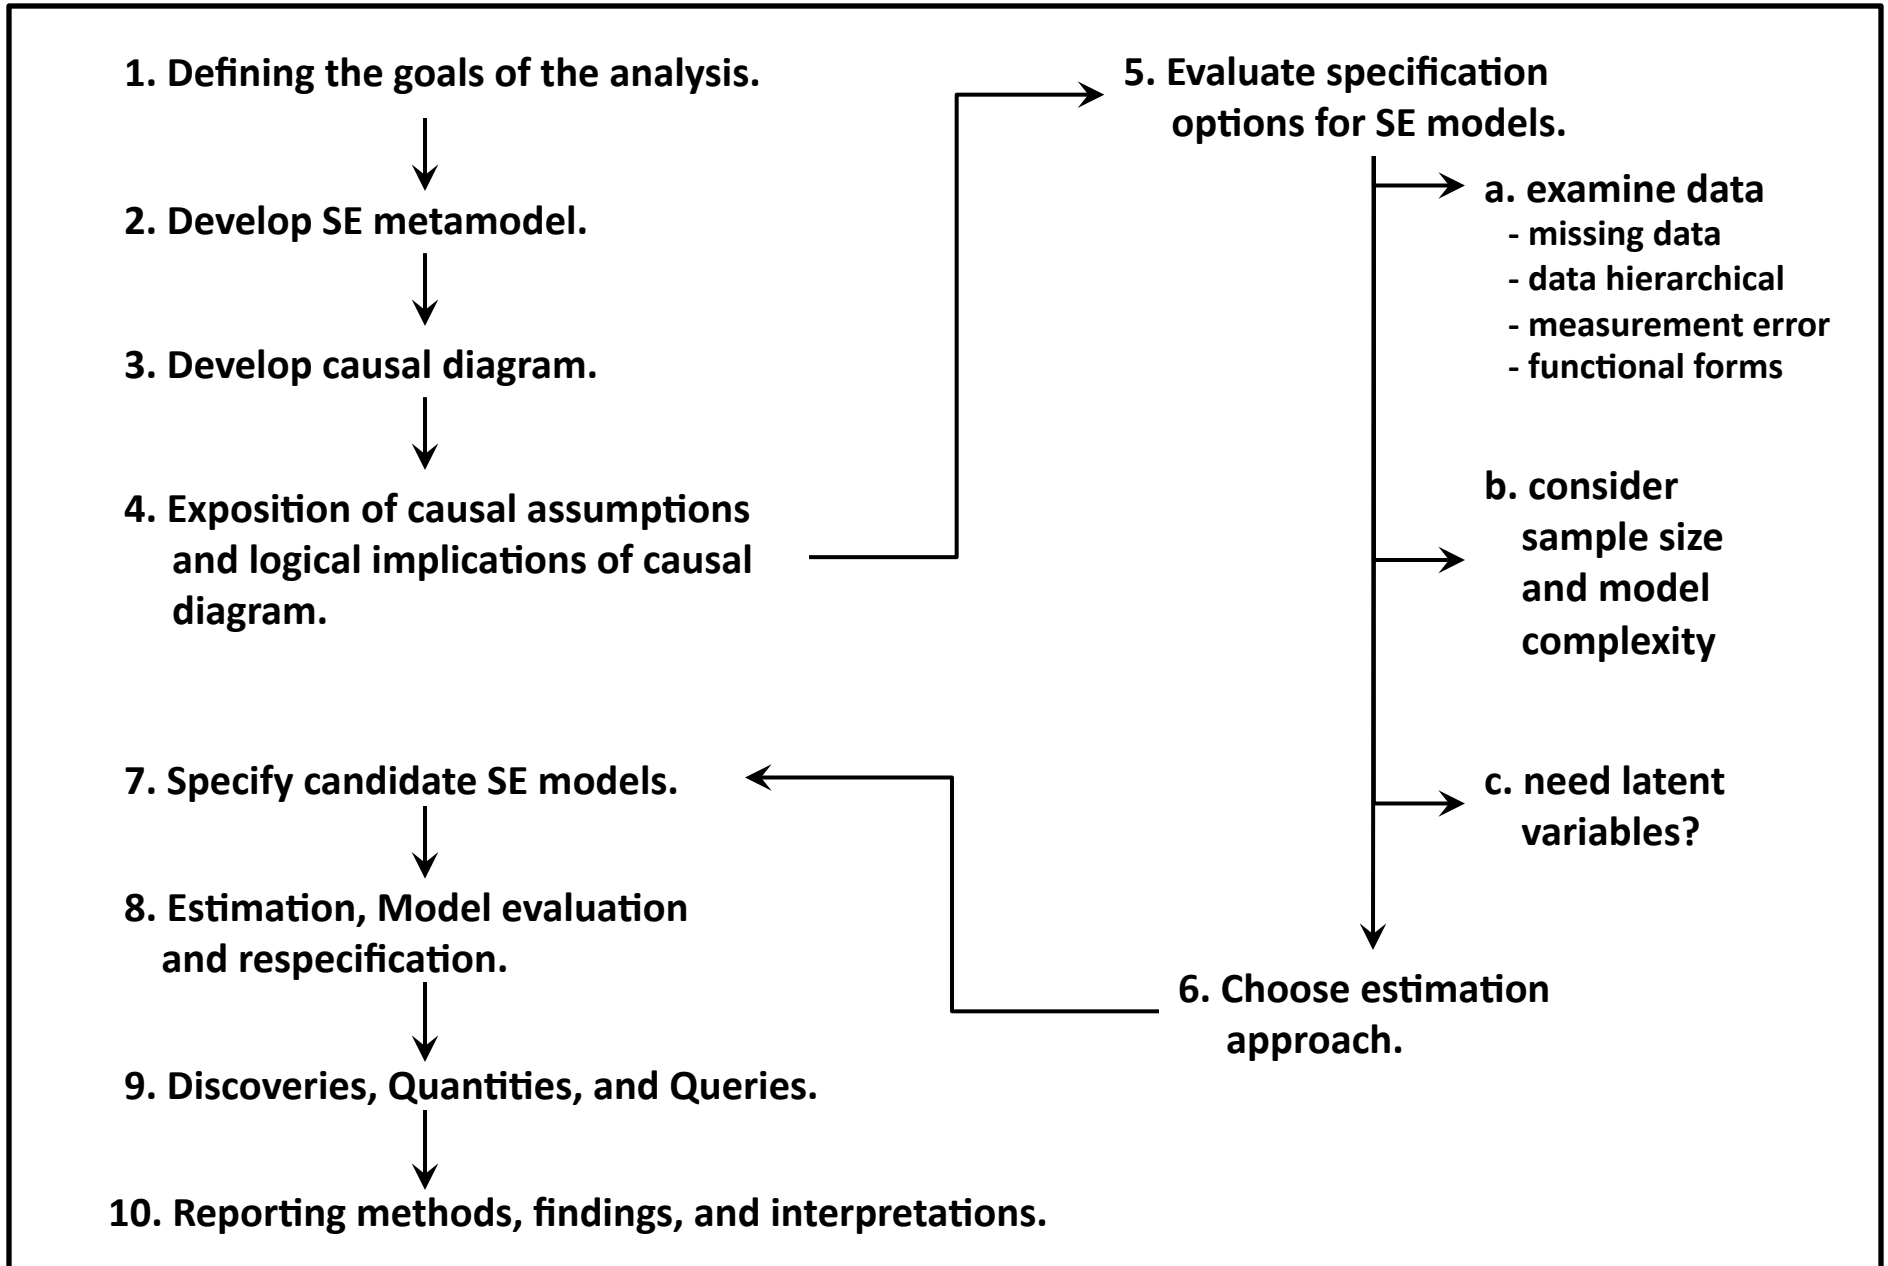

Interpret large direct effects as “proof” of causality

1. Question causal assumptions.
2. Question directionality.
3. Question whether there you have all of the relevant variables included.
4. Could a misspecified model have led to the same result?

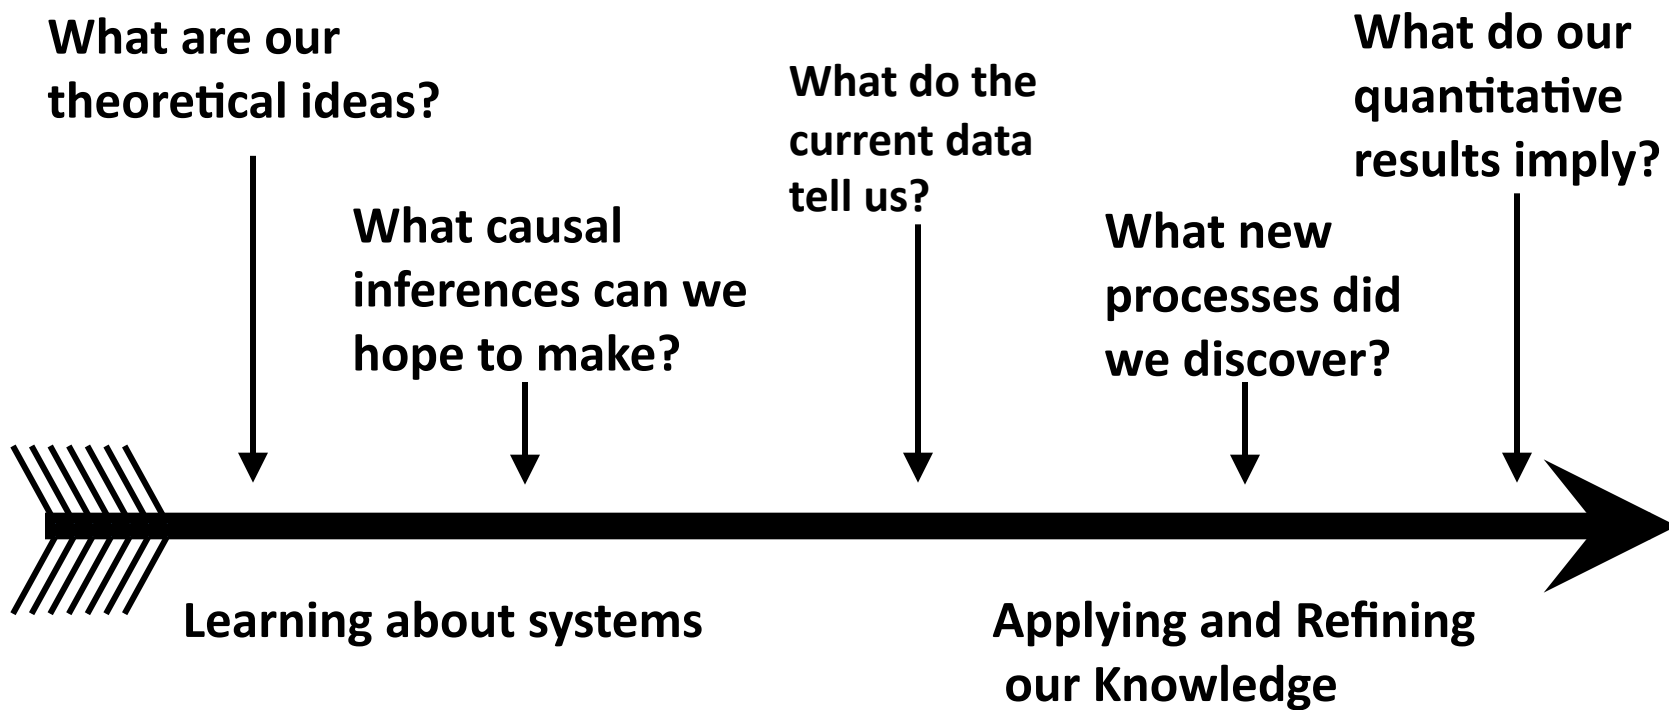

Welcome to the SEM Brigade

A New Framework

An expanded causal inference process

It is likely that no one ever masters anything in which he has not known impotence; and if you agree, you will also see that this impotence comes not at the beginning of or before the struggle with the subject, but in the heart of it.

– Walter Benjamin
